

GENERAL CHARACTERISTICS

The flow switch VM.WPS is **compensated** to operate with fluids with viscosities up to 200 cSt with no significant changes in the calibration set.

The piston has been replaced by a particular sized disk that allows to obtain a reduced annular area of the flow passage. The flow velocity in the measuring chamber is adjusted by this element to obtain a stable movement when the viscosity changes. The combination of the two characteristics, passage area and shape of the plate, made it possible to obtain with this tool a good degree of stability of operation.

In addition a good linearity of measurement was also obtained by introducing into the wall of the cylindrical chamber some appropriate cracks that make the passage area proportional to the increase of the flow rate. The maximum deviation from linearity is equal to 10% of the measured value over the entire range of viscosity for which the instrument is designed.

- Hermetic separation between flow chamber and electric head.
- Good repeatability.
- Good insensitivity to impurities.
- Large-scale calibration.
- Microswitch output contact .
